MTBE Production from Raffinate-1 - Cost Analysis

MTBE E21C
ABSTRACT

This report presents a cost analysis of Methyl tert-Butyl Ether (MTBE) production from raffinate-1 and methanol. The process examined is similar to UOP's Ethermax process for isobutylene etherification. In this process the etherification reaction is conducted in two steps, the first step being a conventional reactor and the second a reactive distillation column. Other established commercial etherification processes with similar configuration, like CBI's CDMTBE, Axens' MTBE Process and Evonik's MTBE Process may as well be represented by the economic analysis presented in this report.

This report examines one-time costs associated with the construction of a China-based plant and the continuing costs associated with the daily operation of such a plant. More specifically, it discusses:

* Capital Investment, broken down by:
  - Total fixed capital required, divided in process unit (ISBL); infrastructure (OSBL), contingency and owner's cost
  - Working capital and costs incurred during industrial plant commissioning and start-up

* Operating cost, broken down by:
  - Variable operating costs (raw materials, utilities)
  - Fixed operating costs (maintenance costs, operating charges, plant overhead, local taxes and insurance)
  - Depreciation

* Raw materials consumption, products generation and labor requirements

* Process block flow diagram and description of industrial site installations (process unit and infrastructure)

Keywords: Etherification Reaction, Steam Cracking C4, Raffinate-1, Fuel Additive, Oxygenates
OPTIONAL ANALYSES & DATA

Intratec offers optional analyses that provide extra information and data about the process approached in this report. Some of them are listed below:

* Capital Investment Details
  - Plant Construction Cost Breakdown per Discipline
  - Site Infrastructure Cost Breakdown per Pieces of Equipment
  - Economic Analysis for Different Capacities
  - Project & Construction Implementation Schedule

* Operating Cost Details
  - Utilities Consumption Breakdown

* Economics for Another Plant Location (defined by client)
  - Economic Analysis in a Country of Choice

Access [www.intratec.us/analysis/mtbe-e21c](http://www.intratec.us/analysis/mtbe-e21c) and find the full list of available optional analyses, as well as respective descriptions, samples and pricing.
ABOUT THIS REPORT

Study Objective

This report presents the economics of Methyl tert-Butyl Ether (MTBE) production from raffinate-1 and methanol. The process examined is similar to UOP's Ethermax process for isobutylene etherification.

The primary objective of this study is to explain the cost structure of the aforementioned process, encompassing capital investment and operating cost figures.

The process design and economics in this report are based on an industrial facility with a capacity of \( \underline{\hspace{2cm}} \) per year, a nominal capacity that is globally competitive.

In addition, the economic assessment, developed for the period \( \underline{\hspace{2cm}} \), assumes the construction of a China-based industrial facility that includes the infrastructure typically required for such a project.

Report Overview

This report is structured into eight main parts which follow a logical sequence. Each of these parts is described below.

By way of introduction, the first part – the current chapter – briefly explains the report itself, its structure and objective. Readers are encouraged to spend a few minutes reading this chapter, so as to make the most of the study.

In the second part, *About MTBE*, the reader will learn the basics of MTBE itself. This chapter also covers its applications and major production pathways.

The third part, *Process Overview*, presents basic aspects of the process studied: products generated, process inputs, and physico-chemistry highlights.

The fourth part, *Industrial Site*, describes an industrial plant based on the process under analysis, in terms of the process unit and infrastructure required. This technical analysis underlies the entire study.

The fifth part, *Capital Investment*, presents all capital costs associated with the process examined, from design and erection of an industrial site to plant startup.

*Operating Costs* of the process are examined in the sixth part. Ongoing costs related to the operation of a unit based on the process are studied, including operating fixed costs, operating variable costs and depreciation.

The seventh part, *Product Value*, targets to estimate the gate cost of the plant final product, by adding corporate overhead costs and a parcel that will guarantee an expected Return On Capital Employed (ROCE). It provides an idea of the minimum price at which the product may be sold, and how competitive it is.

The eighth part, *Process Economics Summary*, summarizes all economic figures presented throughout the report.

Finally, to address any questions or concerns about the methodologies and procedures adopted in the development of this report, the reader is referred to the eighth part, *Analysis Methodology*. 
ABOUT MTBE

Description

Methyl tertiary-butyl ether (MTBE) is a volatile organic compound, mainly used as fuel additive to enhance octane rating and reduce air pollution. It is produced by the reaction of methanol and isobutylene (2-methyl-1-propene) in the liquid state.

The demand for MTBE was largely increased in the late 1970s, amid the phase-out of lead as an octane enhancer. Indeed, MTBE low cost, high octane value, oxygen content and easy incorporation into gasoline lead to a significant increase in its consumption in the 1980s, as a substitute for tetraethyl lead in gasoline. The use of MTBE was also stimulated by the governments for meeting air quality goals, since it reduces motor vehicle emissions, air toxics emissions and pollutants that form ground-level ozone. Since then, MTBE has been mainly produced from mixed butylenes from ethylene crackers and from fluid catalytic crackers, catalytic butane dehydrogenation or tert-butyl alcohol dehydration.

In the 1990s, concerns towards the safety of using MTBE arose in light of contaminations of surface and groundwater, in which the presence of MTBE was detected. Such contaminations were related to leakings from underground storage tanks and pipelines: the MTBE, having high solubility in water and low vapor pressure, readily transfers to the groundwater. In this context, since mid-2000s gasoline manufacturers, to comply with new environmental legislation (particularly in the United States), started replacing MTBE by renewable, safer alternatives, mainly ethanol and ETBE (ethyl tertiary butyl ether).

Nowadays, MTBE is still used as gasoline additive outside of the US, mainly in countries in the Middle East and Asia Pacific. In the United States, MTBE is used in the manufacture of high-purity isobutylene (HPIB), but most of its production targets export markets, mainly Latin America.

![Methyl tert-Butyl Ether](image)

Applications

More than 95% of MTBE is used as an anti-knocking agent in gasoline fuels, due to its low cost, high-octane value and easy incorporation into gasoline.

Apart from gasoline blending, the only use of MTBE on an industrial scale is the production of high-purity polymer-grade isobutylene (HPIB), used in turn in the production of butyl rubber and highly reactive polyisobutylene (HRPIB).

Other minor applications of MTBE include its use as solvent for analytical purposes, and as an extractant, in solvent dewaxing of hydrocarbon oils.
MTBE production pathways are mainly related to the sources of isobutylene consumed. Four major sources of isobutylene are utilized: C4 stream (raffinate-1) from steam cracking units, C4 stream from refinery catalytic crackers after butadiene extraction, on purpose isomerization and dehydrogenation of butane to isobutylene, and the dehydration of tert-butyl alcohol. The following chart presents different pathways for MTBE production.
PROCESS OVERVIEW

This chapter presents technical aspects of the Methyl tert-Butyl Ether (MTBE) production from raffinate-1 and methanol.

More specifically, the current chapter describes the raw materials consumed, the products generated and highlights about the physico-chemistry related to this process.

Product(s) Generated

Process Inputs
Highlights & Remarks

In this section, we discuss various aspects of the process. The reactor is a key component in the process, where the reaction takes place. The reaction is catalyzed by a specific catalyst, which accelerates the reaction rate. The reactor is maintained at a specific temperature to ensure the reaction proceeds at the desired rate. The reactor is also equipped with cooling systems to control the temperature and prevent overheating.

The reactor outlet stream contains a mixture of products and unreacted feedstock. This stream is cooled and sent to the separation section, where the products are further processed to remove impurities and recover the desired products.

The separation section consists of various units, including distillation columns and gas absorbers. These units are designed to分离 the various components of the reactor outlet stream. The separation section is critical in ensuring the purity and quality of the final products.

The purified products are further treated and packaged for downstream use. The packaging process involves various steps, such as cleaning, labeling, and packaging. The final product is then sent to storage or directly to the customer.

The system is designed to be efficient and energy-efficient, minimizing waste and environmental impact. The process is also designed to be flexible, allowing for adjustments based on changing market demands and operational requirements.

In summary, the Highlights & Remarks section provides an overview of the process, emphasizing the key components and steps involved. This section is crucial for understanding the operation and optimization of the process.
INDUSTRIAL SITE

This chapter presents all installations that comprise an industrial site for Methyl tert-Butyl Ether (MTBE) production from raffinate-1 and methanol. The process examined is similar to UOP’s Ethermax process for isobutylene etherification.

The present study was mainly based on:

Introduction

The information presented in this chapter is based on commonly utilized concepts related to the type of installations found within a typical industrial site. These concepts include:

* Production units. Also known as inside battery units, these installations comprise all main processing units of the site necessary to the manufacturing of products. These units are located Inside the Battery Limits (ISBL).

* Infrastructure. Also known as outside battery units or offsite facilities, these installations do not directly enter into the manufacturing of a product. They are support buildings, auxiliary units used for providing and distributing utilities and storage facilities. These units are located Outside the Battery Limits (OSBL).

In order to make a better distinction between these types of installation, a diagram is presented in the next page. It provides an insightful overview of the industrial site as whole and helps to clarify how raw materials and utilities are supplied to the process unit. In addition, it shows how any products or utilities generated in the process are discharged from the process unit.
MTBE Production Industrial Site
**Production Units**

Production units form the core of an industrial site. Comprising the site's battery limits (ISBL), such units may be numerous, complex and involve several pieces of equipment. In this context, the most didactic approach to presenting all production units of a site is through the use of a block flow diagram. Visual information is, in fact, the clearest way to present a chemical process and is least likely to be misinterpreted.

In general, these diagrams consist of a series of blocks, representing unit operations or groups of equipment, connected by input and output streams. In fact, there are no strict standards according to which such diagrams are made.

To facilitate the presentation of the production units under analysis, Intratec developed a block flow diagram according to some standards.

The process areas represented (in light blue) correspond to what is defined as a “functional unit”. Basically, a “functional unit” is a significant step in the production process in which a particular physico-chemical operation (i.e., distillation, reaction, evaporation) occurs. According to this definition, a given functional unit is not associated with a single piece of equipment, but rather with a group of equipment and ancillaries required to perform a particular operation.

Blocks representing process areas also show key technical parameters related to these areas, including: highest operating temperature and pressure, representative material of construction, and other parameters.

As to the process streams represented, there is an indication of their phase when leaving/entering a block. Also, such streams provide a global material balance of the process, normalized by the mass flow rate of the product considered in the analysis. In other words, the number near each stream represents the ratio between its mass flow rate and the output flow rate of the product under analysis.

It is worth noting that areas having no significant impact on the economics of the process may not be included in the diagram. Similarly, some streams may also not be represented. Nevertheless, the diagram presented is still extremely useful in providing readers with an overall understanding and “feeling” of the process studied.

For more information on how the process examined was divided into functional units, the reader is referred to the section on *Production Units* in the “Analysis Methodology” chapter.

**Site Infrastructure**

Infrastructure requirements comprise the offsite facilities, or the units located Outside the Battery Limits (OSBL). The OSBL usually have a significant impact on the capital cost estimates associated with any new industry venture. This impact is largely dictated by, among other things: specific conditions where the industrial site will be erected; the level of integration the new site will have with nearby facilities or industrial complexes; and assurance and promptness in the supply of chemicals.

**Process Units Description**

The process units related to the process under analysis are described based on the above explanation. On the next page, a block flow diagram illustrates the production units examined.
MTBE Production Facility
The process under analysis is briefly described below. For clarity, the description was divided according to the process areas indicated in the diagram.

It is important to mention that some aspects of the process examined are either industrial secrets, not published in patents, or have changed and were not reported in the literature at the time this report was developed. That being the case, the design herein presented is partially based on Intratec process synthesis knowledge such that there may be some differences between the industrial process actually employed and the process described in this study. Nevertheless, the design presented suitably represents the technology examined in sufficient detail to estimate the economics of the technology within the degree of accuracy expected from conceptual evaluations.
In thisoffline testmode, part of the stream is recycled to area 15 and what remains is purged to avoid the build-up of butanes and C5+ hydrocarbons in the process.

This excess purge is sent to feed to other nearby facilities.

- Area 15: Propylene Intermediate Tank

The HD propylene product from depropylenator column is stored in an intermediate tank before being sent to the offshore storage.
Site Infrastructure Description

The infrastructure requirements of the industrial site examined are defined based on the following assumptions:

- Industrial site level of integration. The site is partially integrated, meaning that it is integrated with a nearby petrochemical complex that supplies raw materials (ethylene and propylene) to the site through pipelines.
- Raw materials storage. As raw materials are locally provided, the industrial site does not have storage facilities for raw materials.
- Product storage. The site has storage facilities for the products manufactured.
- Utilities facilities. The process examined is not integrated with the industrial complex in terms of utilities supply. All necessary installations are constructed to supply utilities required by the process.
- Support & auxiliary facilities. The industrial site has its own administrative buildings and auxiliary facilities.

Finally, offsite facilities were divided into areas according to their type/function. These areas are listed in the following pages, as well as the major equipment, systems and facilities included in each of them.
Area 9 - Storage Installations

The scope of this area includes:

(T) Tanks providing a total storage capacity of 30 days for PC propylene product.
This area includes:

1) Cooling water systems, including cooling towers and circulation pumps.
2) Steam generation, boiler feed water treatment systems and supply pumps.
3) Refrigeration system, including heat exchangers, flash vessels, circulation pumps and compressors.

* Area 02: Support & Auxiliary Buildings
Auxiliary buildings and support facilities are comprised of:

1. Central control room
2. Maintenance shops and workshops
3. Laboratories and warehouses
4. Administration and offices
5. Change house and cafeterias
6. Gate house and parking lot
Key Process Input and Output Figures

In accordance with the block flow diagram and the global material balance previously presented, the following tables show key process indicators of the technology examined in this report. These indicators reflect the raw material consumption and the products generation rates per unit of product generated.

Raw Materials Consumption

<table>
<thead>
<tr>
<th>RAW MATERIAL</th>
<th>CONSUMPTION PER OF PRODUCT</th>
<th>UNIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethane</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Methane</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Propane</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Butane</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

It should be noted that estimation of raw material requirements in the conceptual design phase is usually reasonably accurate but tends to be somewhat understated compared to real operations. Losses from vessel vents, unscheduled equipment, inerting systems, physical property inaccuracies, startup, shutdown and other process operations not typically addressed in this phase may increase raw materials consumption.

For detailed figures regarding utilities consumption, reader is referred to the supplemental analysis Utilities Breakdown - MTBE E21C. This optional feature is available at Intratec website.

Labor Requirements

The following table presents the number of operators per shift required to run the equipment of the process examined, as well as the personnel per shift required to directly supervise the operating labor.

<table>
<thead>
<tr>
<th>PERSONNEL REQUIRED</th>
<th>WORKERS PER SHIFT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operator</td>
<td></td>
</tr>
<tr>
<td>Supervisor</td>
<td></td>
</tr>
</tbody>
</table>

The estimates included in this chapter are based on the following assumptions:

* Plant nominal capacity: ___ MTBE per year
* Industrial plant location: China
* Construction on a cleared, level site
* Period of analysis: ______
* IC Index at the period of analysis: ______

The IC Index stands for Intratec Chemical Plant Construction Index, an indicator published monthly by Intratec to scale capital costs from one time period to another. This index reconciles the price trends of fundamental components of chemical plant construction such as labor, material and energy, providing meaningful historical and forecast data for readers.
In the next pages capital costs are described in further detail, and calculated estimates are presented. For more information on the methods used for estimating costs, the reader is referred to the “Analysis Methodology” chapter.

**Fixed Capital**

Also referred as “capital expenditures” (CAPEX), fixed capital constitutes the fraction of the capital investment which is depreciable. It includes Plant Cost and the Owner's Cost, further detailed below.

**Plant Cost**

The plant cost is related to the erection of the industrial site itself. It includes Total Process Capital (TPC) and Project Contingency, as described below.

Total Process Capital encompasses the investment required for the construction of: (1) process areas previously presented in the “Process Block Flow Diagram” (ISBL investment); (2) a process contingency reflecting technical uncertainties associated with limited design data, which may incur capital cost increases (e.g., additional equipment not included in the preliminary design); and (3) the site infrastructure (OSBL Investment), also previously discussed.

Project Contingency, in turn, is included to cover the costs that may arise as the project evolves. Such costs include: project errors or incomplete specifications, labor costs changes, strikes, problems caused by weather, inflation, etc.

PLANT COST

The above table presents the upper and lower limits for the plant cost figures, according to the accuracy range expected from conceptual evaluations presented in this report. The presented range is associated with a confidence level of 90%. In other words, a 90% confidence level means that, for every 100 times the project is actually implemented, the plant cost required will fall into the range predicted with our estimates 90 times.

Owner’s Cost

Besides the plant cost, there are other costs that the owner must account for, such as:

* Initial catalyst load in reactors (if not negligible)
* Purchase of technology through paid-up royalties or licenses
* Miscellaneous costs (pre-feasibility/environmental studies, regulatory and permits, long distance pipelines, etc.)

The aforementioned costs are included as owner’s cost.

The table below presents a breakdown of the owner’s cost. Unless otherwise indicated, all figures presented are in US million dollars (MM USD).

Working Capital

For the purposes of this study, working capital is defined as the funds, in addition to the fixed capital, that a company must contribute to a project. Those funds must be adequate to bringing the plant into operation and meeting subsequent obligations.

Working capital includes: raw materials inventory, products inventory, in-process inventory, supplies and stores, accounts receivable and accounts payable.

The table below presents a breakdown of working capital. Unless otherwise indicated, all figures presented are in US million dollars (MM USD).

Additional Capital Requirements

Several expenses are incurred during commissioning and start-up of an industrial site. These expenses may be related to:

* Employee training
* Initial commercialization costs
* Operating inefficiencies and unscheduled plant modifications (equipment, piping, instruments, etc.)

In addition, expenses with land acquisition and site development must also be accounted for. Such additional costs are not addressed in most studies, but can become a significant expenditure. In the current analysis, these costs are represented by additional capital requirements.

The table below presents a breakdown of additional capital investment. Unless otherwise indicated, all figures presented are in US million dollars (MM USD).

Total Capital Investment Summary

The chart below summarizes all major capital costs discussed thus far, from the design and erection of an industrial site to plant startup.

Capital Investment Summary (USD Million)

For more information about how the capital costs were estimated, the reader is referred to section on Capital Investment Estimating in the “Analysis Methodology” chapter.
OPERATING COSTS

This chapter details all ongoing costs required for Methyl tert-Butyl Ether (MTBE) production from raffinate-1 and methanol. Also referred as operational expenditures (OPEX), these encompass costs associated with the plant operation and depreciation, selling of products, and contribution to corporate functions (e.g., administration and R&D activities). In the current analysis, the operating cost was grouped under three main headings:

* Operating variable costs. Costs directly proportional to the actual operating rate of the industrial site (i.e. raw materials and utilities consumption)

* Operating fixed costs. Operating costs directly tied to the plant capacity, but which do not change with the operating level (i.e., operating labor, supervision labor, maintenance costs, plant overhead)

* Depreciation. Refers to the decrease in value of industrial assets with passage of time

It should be kept in mind that the sum of operating fixed costs and operating variable costs is referred as “cash cost”. The sum of cash cost with depreciation, in turn, is referred to as “total operating cost”.

The graph below illustrates the composition of total operating cost.
The estimates included in this chapter are based on the following assumptions:

* Industrial plant location: China
* Period of analysis:
* Plant nominal capacity: of MTBE per year
* Plant operating rate: hours per year

The plant operating rate assumed leads to an annual output of of MTBE. It is important to mention that this rate does not represent any technology limitation; rather, it is an assumption based on usual industrial operating rates.

In the next pages the operating cost items are described in further detail, and estimates calculated are presented. For more information on the methods employed to estimate the costs presented, the reader is referred to the "Analysis Methodology" chapter.
Operating Variable Costs

Variable costs change in direct proportion to changes in the operating level. Such costs include raw materials and utilities (i.e., steam, electricity, fuel, and refrigeration).

The next table displays the operating variable costs.

Operating Variable Costs Breakdown

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

All costs presented in this table are derived from unit consumptions, detailed in the previous chapter, and pricing information.
Operating Fixed Costs

Operating fixed costs are the costs primarily related to the capacity of an industrial site, but which do not change with operating rate. Such costs include maintenance costs, operating charges, plant overhead, local taxes and insurance.

The table below presents a breakdown of operating fixed costs.

MANUFACTURING FIXED COSTS

Depreciation

Depreciation refers to the decrease in value of industrial assets with passage of time, primarily because of wear and tear. While not a true operating cost, depreciation is considered to be an operating expense for accounting purposes – it allows the recovery of the cost of an asset over a time period.

In this study, the depreciation is USD $______ per $______ of MTBE produced. This calculation was based on the straight-line method and a project economic life of 10 years.

Total Operating Cost

The table below summarizes all operating cost components discussed thus far.

For more information about how the operating cost components were estimated, the reader is referred to the section on *Operating Cost Estimating* in the “Analysis Methodology” chapter.
PRODUCT VALUE ANALYSIS

Heretofore, the capital cost and operating cost related to the process examined were described. In order to provide a more consistent economic analysis of the process examined, all such costs are combined in a single item: “Product Value”.

“Product value” is a term commonly used wherein all costs associated with the manufacture of a product are combined. More specifically, it includes the operating cost (operating variable costs, operating fixed costs, and depreciation), as well as corporate overhead costs and an expected Return on Capital Employed (ROCE).

Product value should not be confused with product price. While product value, as previously mentioned, is calculated based on the costs associated with the manufacture of a product, product price is the actual value as seen in the market. The product value should be seen as a minimum price for which the product could be sold, so as the plant owner can get the expected ROCE.

The graph below illustrates the composition of the product value.
Corporate Overhead

Corporate overhead is associated with costs incurred by a company’s head office such as general administrative costs, research and development activities, market and product distribution.

The table below presents a breakdown of corporate overhead costs.

Corporate Overhead Costs Breakdown

<table>
<thead>

</tr>
</tbody>
</table>

Return on Capital Employed (ROCE)

The ROCE is included to pay the investment made to manufacture target product. This component is based on the expected return on capital employed typically aimed by chemical companies.

This “Expected ROCE Amount” component is, in fact, a measure of the cost of investment required to construct the plant, in terms of US dollars per amount of product.

Most chemical companies aim to achieve a ROCE percentage ranging from 10% to 30% for the construction of a new plant. In this context, the Intratec team usually assumes an expected ROCE percentage in the range of 10% (for established industrial processes) to 30% (for early-stage industrial processes, which inherently involve a larger amount of risk and cost uncertainty). For this specific process a ROCE percentage of ______ was assumed.

This results in an increment of ______ USD/mt in the product value.
PROCESS ECONOMICS SUMMARY

This chapter provides a summary of all capital, operating and non-operating costs related to the process described so far. Also, it presents some remarks about the key aspects surrounding the economic analysis performed.

Product Value Composition

The chart below shows the impact of each cost component on the product value.

Product Value Composition (USD/unit produced)

It is important to emphasize that product value should not be confused with product price. The product value should be seen as a minimum price for which the product could be sold, so as the plant owner can get the expected ROCE according to the assumptions on which the economic analysis was based.

In other words, the product price is a variable calculated based on the costs associated with the manufacture of a product, which is something different from the actual product price seen in the market.

Economic Datasheet

The table on the next page condenses the analysis developed in this report.

### PRODUCT VALUE
Economic Remarks

Due to the presence of unconverted ethylene, propylene refrigeration is used to achieve the low temperature required in the top condenser of the column. The deethylenizer column overhead, consisting mainly of unconverted ethylene, is recycled back to area 12. A small vent stream is purged to avoid the buildup of light paraffins impurities in the process. This vent stream is sold as fuel to other nearby facilities.

The reactor exit stream consists of a mixture of propylene, unconverted ethylene and butanes, butenes, and some C9+ components from side reactions. This stream is sent to area 16.

When unconverted ethylene in the reactor exit stream is not reacted further, the reactor is operating under a condition where ethylene has not been consumed. The reactor is functioning as a recycle reactor, maintaining ethylene production to provide feed for the process. In order to increase propylene yield, a regenerator (i.e., catalyst is added to the reactor) is added to the reactor, similar to a double-burner counter-flow reactor, thus ensuring the overall propylene production.

ANALYSIS METHODOLOGY

Introduction

Intratec distilled its expertise, gained from more than a decade of supporting companies worldwide in the analysis of chemical markets and process economics, and developed a consistent report development methodology.

The methodology ensures a holistic, coherent and consistent techno-economic evaluation, guiding the development of a report that allows readers to fully understand a specific chemical process technology.

In addition to being based on a common methodology, all Intratec reports that approach industrial processes have a common structure, i.e., indexes, tables and charts share similar standards. This ensures that Intratec’s readers know upfront what they will get and, more than that, will be able to compare technologies addressed in different reports.

Our methodology is continuously tested and proven by the many chemical and oil corporations, R&D centers, EPC companies, financial institutions and government agencies that rely on our reports.

The methodology used in the development of this report is illustrated in the diagram presented on the next page.

Bibliographical Research

The report is based on a comprehensive bibliographical research, entirely focused on the industrial process to be examined. Our research encompasses patents, encyclopedias, text books, technical papers and non-confidential information disclosed by licensors, duly reviewed by the Intratec team.

The main goal of this research is to provide a solid understanding of the process examined, which in fact underlies the entire study. During this research, Intratec team identifies the maturity of the process under analysis. Basically, established processes are mature industrial processes, i.e., several plants employing these processes have been constructed worldwide, while new industrial processes are those that have only been employed in a few plants constructed around the world. Finally, early-stage industrial processes are the processes still under development; currently, either no plants have employed such technologies or the designs of the processes themselves have yet to be completed.

Process Overview

The Intratec team’s first goal is to understand the chemical, biological and/or physical transformations occurring in the target process, as well as reactants required and products formation.

Thus, initially, bibliographical research focuses on stoichiometry, conversions, yields and/or selectivity of processes’ main reactions or biological processes, while also addressing the occurrence of side reactions and relevant information about catalyst employed.

Regarding raw materials, the Intratec team identifies minimum quality requirements (e.g. minimum purity, maximum presence of specific contaminants), as well as typical industrial sources. For products, the Intratec team gathers information regarding possible uses and applications, as well as the usual specifications necessary to ensure their suitability for those applications.
Examining an Industrial Site

At this point, the Intratec team examines how an industrial site based on the process under analysis would be, in terms of process units and infrastructure required.

In this step, Intratec team defines a preliminary design of the process under analysis, based on fast techniques for process and capital cost estimation, which rely on reduced design efforts. The main goal is to represent the technology examined in sufficient detail to estimate the economics of the technology within the degree of accuracy expected from conceptual evaluations.

It is important to highlight that some specific technical data are not taken into account neither in the preliminary design defined nor in the economic estimates further calculated. In fact, Intratec Reports are meant to be tools to assist the preliminary economic evaluation of emerging or consolidated industrial processes for producing chemicals, and must NOT be viewed as process design packages, design basis or front end engineering design (FEED) packages.

Process Unit

The Intratec team compiles all knowledge acquired around the process into a process block flow diagram, showing major process areas and main process streams, accompanied by a process description. The process areas correspond to what Intratec defines as “functional units”. Basically, a “functional unit” is a significant step in the process in which a particular physico-chemical operation (i.e., distillation, reaction, evaporation, etc.) occurs. According to this definition, a given functional unit is not associated with a single piece of equipment, but rather with a group of equipment and ancillaries required to perform a particular operation.

Such division in process areas not only facilitates process understanding, but also serves as the basis for further economic analysis development.

While outlining process block flow diagram, the Intratec team also maps key technical parameters related to each process area portrayed, including: highest operating temperature and pressure, representative material of construction of equipment, and other parameters. These parameters serve as inputs for the cost estimating methods used by Intratec, further described in this methodology.

Site Infrastructure

The Intratec team also examines the industrial site in terms of the infrastructure (OSBL facilities) required. More specifically, this analysis identifies installations that are required but do not directly enter into the manufacture of a product (e.g., storage, utilities supply, auxiliary and administrative buildings).

The first step in identifying the required infrastructure is to define the level of integration the industrial site under analysis will have with nearby facilities or industrial complexes. Integration levels primarily impact storage requirements – e.g., a plant that is not integrated needs storage for all raw materials and products, while a plant that is fully integrated with nearby complexes does not need such installations.

The Intratec team assumes a level of integration based on what is most typical for the type of industrial plant examined. So, based on the process analysis previously developed and on how integrated the industrial site will be, the Intratec team defines the OSBL facilities requirements.
Defining Site Requirements

* Key Process Inputs & Outputs

At this point, the main processing steps have been identified and global material balance calculations are performed. This preliminary global material balance leads to the identification of key process indicators, which reflect raw material consumption and products generation rates per amount of the main product manufactured.

It is worth mentioning that estimation of raw material requirements in the conceptual design phase is generally reasonably accurate but tends to be somewhat understated compared to real operations. Losses from vessel vents, unscheduled equipment, inerting systems, physical property inaccuracies, startup, shutdown and other process operations not typically addressed in conceptual design may increase raw materials consumption.

* Labor

Operating labor is associated with the number of operators per shift actually required to run the equipment, while supervision labor is the personnel per shift required to directly supervise the operating labor.

The number of operators and supervisors estimated is based on the type and number of functional units included in the process examined.

Also, it is important to mention that in addition to the operating and supervision labor considered, chemical plants also require other types of labor, not included as an operating cost item. Examples of such labor are: maintenance labor, outsourced labor, technical assistance to operation, plant engineers, restaurant, purchasing, employee relations department, etc.

Capital Investment Estimating

The costs that comprise the capital investment are grouped under three main headings: fixed capital; working capital; and additional capital requirements.

Before estimating such capital investment figures, the Intratec team defines plant nominal capacity according to the process under analysis, considering that the plant should be competitive on a global scale.

Once this assumption has been made, the Intratec team begins the actual estimation of the capital investment figures as follows.

**Fixed Capital**

The fixed capital is related to the erection of the industrial site itself. Also referred as “capital expenditures” (CAPEX), the fixed capital constitutes the fraction of the capital investment which is depreciable.

It is composed of Plant Cost and Owner's Cost, described below.

* Plant Cost

The Plant Cost comprises the costs directly, or indirectly, associated with the construction of the plant itself. It includes (1) Inside Battery Limits (ISBL) Investment, (2) Process Contingency, (3) Outside Battery Limits (OSBL) Investment and (4) Project Contingency, estimated as follows.
(1) Inside Battery Limits (ISBL) Investment

The ISBL investment is the fraction of the fixed capital associated with the construction of all process areas (functional units) portrayed in the process block flow diagram.

Initially, to calculate ISBL investment, the Intratec team approaches each process area individually. The fixed capital of a given area is estimated based on the respective process parameters detailed in the block flow diagram (flow rates, pressure and temperature conditions, materials of construction, complexity), through the use of specific preliminary cost models.

It is worth noting that the Intratec cost models were founded on a number of established cost estimating methods, based on mathematical and statistical processing of an extensive volume of actual cost data of well-known industrial processes and functional units. In fact, such a massive refining of established methods has led to robust cost models, continuously tested and proven for more than a decade by major global companies that rely on Intratec’s cost estimates of industrial processes.

So, from the process parameters identified, the output of Intratec cost models is the fixed capital for each functional unit, including all costs associated with the erection of those units: direct material and labor costs, as well as indirect costs, such as construction overheads, including: payroll burdens, field supervision, equipment rentals, tools, field office expenses, temporary facilities, etc.

In the case of nonstandard functional unit, additional research is conducted and the capital cost is estimated from the use of specialized engineering design software or through quotations provided by equipment suppliers.

Finally, the sum of all fixed capital figures, associated with the functional units examined, leads to the total ISBL investment figure.

(2) Process Contingency

Process contingency is utilized in an effort to lessen the impact of absent technical information or the uncertainty of that which is obtained. That being the case, the reliability of the information gathered, its amount and the inherent complexity of the process are significant to its evaluation. Errors that occur may be related to:

a. Addition and integration of new process steps

b. Uncertainty in process parameters, such as severity of operating conditions and quantity of recycles

c. Estimation of cost through scaling factors

d. Off-the-shelf equipment

Hence, process contingency is a function of the maturity of the technology and the reliability of the information gathered for the analysis. This value typically falls between 5% and 20% of ISBL investment.

(3) Outside Battery Limits (OSBL) Investment

The OSBL investment is the fraction of the fixed capital associated with the construction of all infrastructure (storage, utilities, auxiliary units and buildings) required.

The Intratec team employs cost estimation models similar to those previously described for estimating OSBL investment, i.e., initially, a preliminary design of OSBL equipment is defined based on the process requirements. This preliminary design information serves as an input to Intratec’s cost estimation models.
(4) Project Contingency

Project Contingency is included to cover the costs which may arise as the project evolves, related to: project errors or incomplete specifications, labor costs changes, strikes, problems caused by weather, inflation, etc.

Project contingency is largely dependent on the plant complexity and technology maturity, identified during initial research. The following table shows how project contingency varies according to such aspects.

## Project Contingency

* Owner’s Cost

In this study, the Owner’s Cost is defined as those expenses that, despite not being associated with the construction of the plant itself, should be included in the Fixed Capital (the depreciable capital), as they are required to make the plant operational. The Owner’s Cost comprises the (1) initial charge of chemicals & catalysts (if required), (2) Prepaid Royalties and (3) Miscellaneous Costs, estimated as follows.

(1) Initial Charge of Chemicals & Catalyst

This cost is only accounted for if the process requires an inventory of a specific chemical and/or catalyst that will last more than a year and represents a significant expense. In this case, it is a depreciable expense and should not be included in the working capital (described further), which, in turn, corresponds to the funds used in its day-to-day operation.

(2) Prepaid Royalties

Royalty charges on portions of the plant are usually levied for proprietary processes. A value ranging from 0.5 to 1% of the plant cost is generally used.

(3) Miscellaneous Costs

A value ranging from 5% to 10% of the plant cost is generally used to account for:

a. Preliminary planning studies, HAZOP studies and environmental reviews
b. Legal costs, rights of way, permits and fees
c. Long distance pipelines, transport equipment and plant vehicles
d. Initial stock of maintenance
e. Owner’s engineering (staff paid by owner to evaluate the work of the company in charge of plant construction)
f. Owner’s contingency
* Fixed Capital Validation

Depending on the availability of information about the process examined, the Inratec team utilizes three different methods to double-check fixed capital estimates:

(1) Published investment data, related to the construction of industrial plants of that process worldwide (adjusted in time, location and capacity); and/or

(2) Fixed capital of similar plants (adjusted in time, location and capacity); and/or

(3) Reverse engineering methods, i.e., the fixed capital is calculated based on the known profitability of the process examined.

**Fixed Capital Estimate Accuracy**

The accuracy range for the fixed capital cost estimate obtained according to the methods hereby presented is -15% to -35% on the low side and +25% to +60% on the high side. This accuracy range is mainly influenced by:

* Reliability and amount of the information available

* Examined technology maturity

* Degree of extension of the study

As previously explained, the fixed capital is estimated based on the preliminary design of functional units which, in turn, relies on a process scheme. The greatest essential uncertainty lies in the basic conception of this process scheme. The level of uncertainty varies broadly among published information and from steps of a process in a given research. In some instances, sufficient information may not be available to support rigorous estimation, thus, only basic design methods are warranted.

The maturity of the examined technology, in turn, also plays an important role in the fixed capital estimates. Early-stage processes require an extra level of caution.

In addition, the extension of the analysis helps enormously to reduce uncertainties and improve the accuracy of the cost estimation. Detailed studies are crucial to achieving more precise estimates.

Finally, the non-uniform spread of accuracy ranges (+50 to − 30 %, rather than ±40%, e.g.) is justified by the fact that a lack of available information usually results in underestimating rather than overestimating project costs.

**Working Capital**

For the purposes of this report, working capital is defined as the funds, in addition to the fixed capital, that a company must contribute to a project. Those funds must be adequate to getting the plant into operation and meeting subsequent obligations.

The initial amount of working capital is regarded as an investment item. The Inratec team uses the following items/assumptions for working capital estimation:

* Accounts receivable. Products shipped to but not paid for by the customer, represents the extended credit given to customers. It is estimated as a certain period — in days — of total operating cost (including depreciation and excluding by-product credits, if any) plus corporate overhead.
* Accounts payable.  A credit for accounts payable such as feedstock, chemicals, and packaging materials received but not paid to suppliers.  It is estimated as a certain period – in days – of operating cash cost (excluding by-product credits, if any) plus corporate overhead.

* Product inventory.  Products in storage tanks.  The total amount depends on sales flow for each plant, which is directly related to plant conditions of integration to the manufacturing of the product’s derivatives.  It is estimated as a certain period – in days – of total operating cost (including depreciation and excluding by-product credits, if any) plus corporate overhead.

* Raw material inventory.  Raw materials in storage tanks.  The total amount depends on raw material availability, which is directly related to plant conditions of integration to raw material manufacturing (estimated as a certain period – in days – of raw material delivered costs).

* In-process inventory.  Material contained in pipelines and vessels, except for the material inside the storage tanks, assumed to be 1 day of cash cost (excluding by-product credits, if any) plus corporate overhead.

* Supplies and stores.  Parts inventory and minor spare equipment (estimated as a percentage of operating labor and supervision and maintenance cost).

* Cash on hand.  An adequate amount of cash on hand to give plant management the necessary flexibility to cover unexpected expenses.  It is estimated as a certain period – in days – of cash cost (excluding by-product credits, if any) plus corporate overhead.

**Additional Capital Requirements**

There are certain one-time expenses related to bringing a process on stream.  From a time standpoint, a variable undefined period exists between the nominal end of construction and the correct operation of the plant (e.g. production of quality product in the quantity required).  This period is commonly referred to as start-up.

During the start-up period, expenses are incurred for operator and maintenance employee training, temporary construction, auxiliary services, testing and adjustment of equipment, piping, and instruments, etc.  Intratec’s method of estimating start-up expenses may consist of the following components:

* Labor training.  Represents costs of plant crew training for plant start-up, estimated as a certain number of days of total plant labor costs (operators, supervisors, maintenance personnel and laboratory labor).

* Commercialization costs.  Commercialization costs are those associated with marketing the product and include developing a market plan, establishing a distribution network and devising a customer support strategy.  Those costs are dependent on how integrated the plant is with consumer facilities and on the maturity of the product – how established and well-known it is.  These costs range from 0.5% to 5% of annual cash cost (excluding by-product credits, if any) plus corporate overhead.

* Start-up inefficiency.  Takes into account those operating runs when operation cannot be maintained or there are false starts.  Start-up inefficiency varies according to the process maturity: 5% for early-stage processes, 2% for new processes, and 1% for established processes, based on annual cash cost (excluding by-product credits, if any) plus corporate overhead.

* Unscheduled plant modifications.  A key fault that can occur during the start-up of the plant is the risk that the product(s) may not meet market specifications.  Then, equipment modifications or additions may be required.
Pricing & Wage Rates Definition

In order to calculate fixed and variable operating costs, the Intratec team collects average transaction prices of raw materials and average operators’ wage rates in the region examined in the study.

The prices are based on trade statistics issued by official government agencies, over the time period considered. Pricing information is checked to verify consistency, but issues like differences in product qualities, discounts related to volumes, or contractual negotiations are not considered.

However, for some chemicals, there are no trade statistics (e.g., intermediate chemicals that are not traded because of transportation issues, but are usually generated and consumed onsite). In those cases, the Intratec team assumes a transfer price that considers all the costs related to the manufacturing of that product plus an amount to pay the investment made to manufacture it.

The operators’ wage rates are based on data published by official government agencies.

Operating Variable Cost

Variable costs change in direct proportion to changes in the operating rate. Examples of common variable costs include raw materials and utilities.

The Intratec team calculates the operating variable costs of the plant under analysis from previously identified process input and output figures and historical pricing data, as follows:

\[
\text{Operating Variable Costs} = \text{Net Raw Material Costs} + \text{Net Utilities Costs}
\]

* Net Raw Materials Costs

“Net raw material costs” are the difference between raw materials costs and credits from by-products generation, as expressed in the formula below.

\[
\text{Net Raw Material Costs} = \text{Raw Material Costs} - \text{By-product Credits}
\]

The raw materials costs, in turn, are estimated by multiplying process’ consumption figures by the respective raw material prices in the region considered. The formula below illustrates the raw materials costs calculation:

\[
\text{Raw Material Costs} = \sum (\text{Raw Material Price} \times \text{Raw Material Consumption})
\]

By-products credits were estimated in a similar way, based on process’ input and output figures and pricing data.

* Net Utilities Cost

In this report, the utilities cost component encompasses costs related to a plant’s consumption of steam, electricity, fuel, and refrigeration. These utilities requirements, in turn, are estimated through correlations internally developed by the Intratec team that were refined from a well-established method reported in technical literature by Mardsen et al. related to chemical process industries. (See “References” chapter)
Operating Fixed Cost

Operating fixed costs are all the costs related to the plant operation that are not proportional to the plant operating rate. They are estimated as the sum of the following items:

* Operating labor. This item accounts for the total costs of plant operators actually required to run the equipment. This cost includes wages, burdens and benefits. The annual operator cost is obtained according to the formula: number of operators per shift x number of shifts per day x operator hourly wage rate x hours worked per week x weeks per year.

* Supervision. Accounts for the costs of field supervision labor, including wages, burdens and benefits. The annual supervision cost is obtained according to the formula: number of supervisors per shift x number of shifts per day x supervisor hourly wage rate x hours worked per week x weeks per year.

* Maintenance cost. This item accounts for the costs related both to the labor and material costs related to the maintenance of the plant. It is calculated as a percentage of the fixed capital, ranging between from 1 to 5% of TFC per year. This figure is primarily based on the type of equipment employed and the maturity of the process.

* Operating charges. This category includes operating supplies (i.e., consumable items such as charts, lubricants, test chemicals, etc.); packaging; laboratory supplies and laboratory labor. It is calculated as a percentage of the total labor cost (item operating labor + item supervision).

* Plant overhead. This item comprises all other non-maintenance (labor and materials) and non-operating site labor costs for services associated with the manufacture of the product, including: outsourced labor; technical assistance to operation; plant engineers; restaurant; recreation; purchasing; employee relations department; and janitorial. It is calculated as a percentage of the sum of total labor and maintenance costs.

* Property taxes and insurance. This cost is associated with the local property taxes charged by governments on commercial land or buildings as well as the cost of insurance to cover third party liabilities and potential plant damages. It is calculated as a percentage of the fixed capital per year.

Depreciation

Depreciation refers to the decrease in value of industrial assets with the passage of time, primarily due to wear and tear. While not a true operating cost, depreciation is considered to be a operating expense for accounting purposes – it allows the recovery of the cost of an asset over a time period.

In this report, depreciation is calculated based on the straight-line method, according to which the cost of an asset is uniformly distributed over its lifetime. The Intratec team assumes a depreciation of 10 % of the fixed capital per
Product Value Estimating

Heretofore, capital investment and operating cost of the process examined were estimated. If the examined process targets to produce a chemical, the next step in the methodology is the development of a more consistent analysis, encompassing all costs estimated so far, and aiming to estimate the value of this target product generated.

In this context, all costs estimated are combined in a single item: the “Product Value”. More specifically, the product value results from the sum of operating costs (i.e., operating variable costs, operating fixed costs, and depreciation) with corporate overhead, and a return on capital employed (ROCE), a parcel which reflects the capital investment. The formula below expresses the product value calculation.

\[
Product\ Value = Operating\ Variable\ Costs + Operating\ Fixed\ Costs + Depreciation + Corporate\ Overhead + Expected\ ROCE\ Amount
\]

where all components are expressed in US dollars per amount of product.

The corporate overhead and the ROCE are estimated as follows.

Corporate Overhead

Corporate overhead represents costs incurred by a company’s head office not directly related to the process operation and is estimated as the sum of the following items:

* Administration costs. This item comprises the executive and administrative activities. It includes salaries and wages for administrators, accountants, secretaries, legal costs, communications, office maintenance and other costs associated with the company’s head office. It is calculated as a percentage of the sum of total labor and maintenance costs.

* Marketing & distribution. This is related to the costs associated with the distribution and sales (sales personnel, advertising, technical sales service) of the products manufactured in the plant. This cost is calculated as a percentage of the operating cash cost (excluding by-product credits, if any), considering the plant operating at full capacity, which varies according to the process maturity and the level of integration with product consumers.

* Research & development. This is associated with the research activities related to the process and products. It includes salaries and wages for personnel and funds for machinery, equipment, materials and supplies related to the research and development activities. This cost is calculated as a percentage of the operating cash cost (excluding by-product credits, if any), considering the plant operating at full capacity and will vary according to the process maturity.

Return on Capital Employed (ROCE)

The expected ROCE amount is a component which reflects the capital costs of a given process into its product value. This component is based on the expected return on capital employed typically aimed by chemical companies. It is calculated by multiplying capital costs by the expected ROCE percentage, divided by the total amount of product manufactured:

\[
Expected\ ROCE\ Amount = Capital\ Costs \times Expected\ ROCE\ Percentage / Product\ Annual\ Production
\]

This “Expected ROCE Amount” component is, in fact, a measure of the cost of investment required to construct the plant, in terms of US dollars per amount of product.
Most chemical companies aim to achieve a ROCE percentage ranging from 10% to 30% for the construction of a new plant. In this context, the Intratec team assumes an expected ROCE percentage of 10% for established industrial processes.

In contrast, a 30% expected ROCE is assumed for early-stage industrial processes, as such processes inherently involve a larger amount of risk and cost uncertainty. It should be noted that the risk taken into account here is limited to the technical risk associated with the process uncertainties. Other venture risks were not considered, such as business environment, product market changes, increased competition, raw materials and product prices variations, change in government policy, etc.

Finally, it is also important to mention that product value must not be confused with product price. While the product value is calculated based on operating cost, corporate overhead and expected ROCE, the product price is the actual value practiced in market transactions.

**Estimates Limitation**

The cost estimates presented refer to a process technology based on a standardized design practice, typical of major chemical companies. The specific design standards employed can have a significant impact on capital and operating costs. In this context, cost estimates calculated by Intratec team naturally have limitations.

In fact, the accuracy range for operating cost estimated in the present study is -10% to -20% on the low side and +10% to +20% on the high side, depending on the maturity level of the process examined. The presented accuracy considers a confidence level of 90%, which is consistent with the type of conceptual evaluation that this study aims to provide.

Also, it is to be noted that the basis for capital and operating costs estimation is that the plant is considered to be built in a clear field with a typical large single-line capacity. In comparing the cost estimates presented with actual plant costs and/or contractor’s estimate, the following must be considered:

* Minor differences or details (many times, unnoticed) between similar processes can noticeably affect cost.

* The omission of process areas in the design considered may invalidate comparisons with the estimated cost presented.

* Industrial plants may be overdesigned for particular objectives and situations.

* Rapid fluctuation of equipment or construction costs may invalidate cost estimate.

* Market price fluctuations may invalidate operating cost estimate.

* Equipment vendors or engineering companies may provide goods or services below profit margins during economic downturns.

* Specific locations may impose higher taxes and fees, which can impact costs considerably.

Furthermore, no matter how much time and effort are devoted to accurately estimating costs, errors may occur due to the aforementioned factors, as well as cost and labor changes, construction problems, weather-related issues, strikes, or other unforeseen situations. This is partially considered in the project contingency. Finally, it must be said that an estimated project cost is not an exact number, but is rather a projection of the probable cost.
ABOUT INTRATEC

Our Business

In operation since 2002, Intratec is a leading provider of chemicals and utilities pricing data and production cost reports.

We are a group of process engineers, market researchers and cost estimators with extensive industry experience. In a nutshell, our business is about providing up-to-date and independent studies detailing production costs of chemicals and utilities, as well as chemical commodities and utilities pricing data.

With a set of well-designed and cost-effective offerings, we serve a diverse group of clients from all over the world. Small companies and independent consultants often choose our +900 reports to ascertain the costs of a specific production process. By utilizing our reports subscription plans, leading global companies have a repository of reliable and easy-to-compare process economic analyses. Subscribers to our chemical pricing data monitor monthly prices of +40 chemical commodities and utilities.

Intratec also supports clients needing more tailored analyses and data. We provide customized and yet cost-effective services through a structured work methodology, refined over 15 years and based on pillars like conducting services remotely, objective communications and no confidential data exchange.

Our studies and data have been used by our clients in multiple ways, such as:

* To obtain estimates of capital and operating costs of chemical plants
* To learn about the economic potential of R&D breakthroughs
* To screen and assess industrial investment options
* To monitor chemicals and utilities prices

Our Reports Store

Intratec offers more than 900 up-to-date reports examining production costs of chemicals and utilities. Our portfolio covers +300 chemicals and utilities, including basic chemicals and inorganics, plastics, fibers and rubbers, green chemicals and biofuels, fertilizers, specialties and more.

In short, each report examines the economics of one specific production process, presenting key information such as raw materials consumption, capital investment and operating costs. Intratec Reports may be acquired individually or through one of our subscription plans.
Find below the chemicals covered in Intratec reports. For a more complete and updated list, reader is encouraged to visit our online store at [www.intratec.us/production-cost-reports-store](http://www.intratec.us/production-cost-reports-store).

Our Reports Subscription Plans

Through Intratec Subscription Plans, every month customers receive new reports and benefit from:

* Professional, independent & up-to-date analyses
* Repository of easy-to-compare process economic analyses
* Best value for price - reports are acquired for a fraction of the cost!

See below available subscription plans.

Standard Plan

With this plan, subscribers get online access to 3 new reports every month for 12 months, covering Basic Chemicals, Inorganics, Fertilizers, Plastics, Fibers, Rubbers, Green Chemicals, Biofuels and Specialties. Subscribers view the reports in web format. The new reports delivery schedule, for the upcoming 12 months, is presented at Intratec website.

Premium Plan

This plan has all Standard Plan features, plus (i) extra analyses for each report delivered (Utilities Consumption Breakdown; Plant Construction Cost; Breakdown per Discipline; Economic Analysis for Different Capacities; Project & Construction Implementation Schedule); (ii) download feature for reports and optionals; and (iii) technical support. It is worth to highlight that only subscribers of the Premium Plan are able to download reports and analyses as PDF files.

For more information on our reports subscription plans, please visit www.intratec.us/production-cost-reports-subscription.
TERMS OF USE

Data, information, reports, tools, analyses and/or models (“products”) herein presented are prepared on the basis of publicly available information and non-confidential information disclosed by third parties. Third parties, including, but not limited to technology licensors, trade associations or marketplace participants, may have provided some of the information on which the analyses or data are based.

The products herein presented are developed independently by Intratec and, as such, are the opinion of Intratec and do not represent the point of view of any third parties nor imply in any way that they have been approved or otherwise authorized by third parties that are mentioned in this report.

Intratec conducts analyses and prepares products for readers in conformance with generally accepted professional standards. Although the statements in this product are derived from or based on several sources that Intratec believe to be reliable, Intratec does not guarantee their accuracy, reliability, or quality; any such information, or resulting analyses, may be incomplete, inaccurate or condensed. All estimates included in this product are subject to change without notice. This product is for informational purposes only and is not intended as any recommendation of investment.

Reader agrees it will not, without prior written consent of Intratec, represent, directly or indirectly, that its products have been approved or endorsed by the other parties. In no event shall Intratec, its employees, representatives, resellers or distributors be liable to readers or any other person or entity for any direct, indirect, special, exemplary, punitive, or consequential damages, including lost profits, based on breach of warranty, contract, negligence, strict liability or otherwise, arising from the use of this product, whether or not they or it had any knowledge, actual or constructive, that such damages might be incurred.

Reader agrees that Intratec retains all rights, title and interest, including copyright and other proprietary rights, in this product and all material, including but not limited to text, images, and other digital files, provided or made available as part of this product.

The Reader is responsible for ensuring that copyright laws are adhered to at all times. Digital products may be supplied watermarked with the Purchaser’s name, email, and/or company.

Reader may, in the course of its business, create its own analyses incorporating information and/or data presented in Intratec products, provided that: (i) Reader acknowledges Intratec as a data source in relation to such analyses created; and (ii) Reader does not use or authorize the use of such analyses created in products that are competitive with Intratec products.

The Reader further agrees to refrain from any general release of the information presented in this product, so as to constitute passage of title into the public domain or otherwise jeopardize common law or statutory copyright.
